THE 2017 STC Higher Education Indexes

Editorial

In developed countries, the economy rests mainly on the productivity of the minds populating the nation. Human capita is the greatest asset, and higher education is key in maintaining competitiveness.

Like in other spheres of business, your cost of production will influence whether you would rather look to import or produce yourself. A private university in the U.S. will cost you a quarter of a million dollars for an undergraduate diploma. Whether you paid that amount out-of-pocket or took out a loan, the bottom line is that you will look for a return on investment after graduation, one that will help you recuperate that vast amount you dished out. The cost of higher education influence wages paid, and higher cost equates to a higher wage. The wage bill is usually the highest cost a company can have, and it's important when a government increases its tuition fees to understand the impact it can have down the line in the equilibrium, affecting the competitiveness of its private sector. Countries like the U.S. and the UK have relatively high education costs, thereby reducing access to education for the lower class. Meanwhile, it offers higher wages that attract many foreign workers. Instead of concentrating all its efforts on producing its own qualified workers at a high cost, it relies also heavily on attracting foreign talents that they can, in turn, pay less than local workers. What gives the two richest cities in the world, New York and London, the pulling power to

attract top performers is their ability to pay more. In the cases of fast-developing countries, even ones with the funds to invest in improving their higher education system, the expertise might be lacking and it could take decades before it reaches a competitive level of value-added. This is highlighted in Gulf countries, where the local production of qualified workers is too low to sustain growth. These countries are known for having the highest immigration rate in the world, with more than 50 percent of their

residents being foreigners. The interesting contrast is between those deemed qualified and the unqualified labour. The wage difference between the engineer and the construction worker is more than tenfold. This highlights, in part, the value those societies place on "qualifications" due to their scarcity.

We define an efficient higher education system as one that balances quality and accessibility. But like the U.S. and the UK, to each its own. Since these countries cannot compete on cost because of their elitist approach, they have put their efforts into producing the highest quality products. Each year, American and English universities have monopolized the top of the QS University rankings and certainly believe they are going the most appropriate path as they attract top students from overseas. Each of our rankings takes a perceptive, and it's important to understand those rankings from that perspective.

When one says education needs to produce the worker of tomorrow, everyone who hears it might tell you they understand that phrase clearly. But how does that really translate in our education system? Everyone will be quick to put forward that if we require more doctors in the future, we should start educating more doctors today. But much more has changed with our rapidly evolving technology. A professional today relies much less on memory than one did in the past. Our access to information at the tips of our fingers has reduced our need for memory. Now we value creativity, risk management, and rational thinking as tools that will enable the user to reach a higher level of productivity. We would much rather equip with "qualifications" those with these natural abilities rather than those who simply have a good memory. When you look at a system like France's higher education system, where the top universities are restricted to a very few because of their small size and very low acceptance rates, you know that those few being selected need to be the right ones for the future. Such a system leaves a very small margin of error. If to get to those top universities you require top grades, and the school's grading system is overwhelmingly a measurement of the child's learning ability, your system is lagging from the present that values creativity and rational thinking. Most countries are still lagging, as it takes a long time for governments to realise the inefficiency, consult for solutions and start addressing the issue. The future top performer will be much less reliant on his learning ability than before, especially in the highly developed countries where the need to innovate and optimize is a must in order to stay competitive. It's a natural process: certain abilities decrease in value as others increase. The same is true with expertise in certain fields. A country today can't educate its human capita like it did 20 years ago because that world has changed ... and is changing faster and faster still.

What is a successful education system? It really depends on if you bank on grassroots or quality imports.

The grassroots system is about educating your own population; a success in that sense is defined by offering accessible quality higher education. This means a top university that is accessible both financially and academically. If you are an industrialized country, you are looking at above 40 percent of labor force with tertiary education. For example, Canada, Germany, or Switzerland.

You are better off relying on quality imports if your education system would be very expensive to subsidize and you want to make sure that those who do get access to your top universities are some of the world's top students. Your design is to attract talent when they are the most accessible and adaptable. For that you will need to have some of the best universities of your region, if not the world, to attract top students from neighboring countries. You are doing a massive brain drain of talent, at the expense of your local population, which might not find higher education accessible to them. For example, the USA and the UK.

The STC Higher Education Indexes

The 2017 STC Higher Education Indexes is a collection of six very different rankings measuring the accessibility of quality higher education and the production of high-value qualified labour around the world, accessibility being financially and academically. Those rankings are categorized in the University Indexes and the Human Capita Indexes. Each of them has a different index calculation and highlights very different results.

The University Indexes are composed of two rankings, one ranking universities and the other ranking cities according to the perception of individuals. The Human Capita Indexes take the perspective of the corporations and governments. It is divided into segments ranking cities and countries. Each of these segments offer an "Elite" ranking with universities with a QS score above 80.

The STC University Index – University Ranking

This index measures the accessibility, both academic and financial, of quality education offered by each university. Our index looks for balance between those three factors to facilitate the choice for an individual. You can go through the ranking and view which university offers the best riskv-to-reward ration and filter by university cost and academic accessibility. The ranking will hopefully permit you to make the most rewarding choice in selecting a university for yourself or your children.

In that perspective, Switzerland takes the cake this year yet again with ETH Zurich remaining in first position for the third year running since we started the ranking. World-class universities are at a bargain and very much academically accessible in Switzerland, with EPF of Lausanne rising to second place, over-

taking Montreal's McGill College. English-speaking countries are very well represented in the top of the ranking, with the UK, Canada, Australia and the U.S. Compared to last year there wasn't any singular change at the top, but a few universities have dropped and others have gained. The main factor of changes was from the QS score. Drops or gains at the top of the QS ranking translated was nationwide as, for example, most of the universities in the UK, Australia or Canada dropped points compared to last year's score.

Keep in mind that the quality attribute is rated by QS

and has a general spectrum. Certain "schools" such as law, engineering or medicine can be rated differently from their general QS university rating. This can apply to undergraduate and graduate studies as well, where a university might excel in one but not the other. Our top three rated universities are technical schools, thereby perhaps not offering many programs outside engineering. The same variation can apply to tuition fees and academic accessibility. Making a final choice of university always requires detailed research of programs; we only try to point toward the right direction.

The STC University Index – City Ranking

This index is relevant to individuals and especially families when considering higher education as an important factor when relocating to a new city. The same way we have measured the accessibility of quality education offered by each university, we have Our university ranking and city ranking for individuals takes the perspective of a parent. When your child is yet to be born, you cannot know if he/she will be a top student or if he/she could be accepted to very selective universities in the future. When a family looks to relocate, choice of quality higher education is an important criterion in the selection process. There is a risk/reward nature that needs to be applied in the decision, as is it wise to settle in a city with one university if that establishment only accept the top 1 percent of its applicants? We rank our universities and cities in the same manner, asking the question, "Who will provide my child with a quality university education by making it accessible?" And accessibility is probably what matters above all: You can live right in front of Harvard, but your child might never

be able to step foot in its classrooms. Boston highlights the purpose of the ranking excellently. The two best-rated universities in the world are in Boston: Harvard and MIT. But both are extremely hard to get into. The more accessible universities in the city in academic terms are not ranked anywhere near the top. If you chose to relocate to Boston in the hope that your children will attend Harvard or MIT only to fail to get accepted, you might have to settle for a university far outside the Elite at \$45K a year. That would not have been an optimal choice in term of risk versus reward. You would usually go for a far safer bet with good returns, namely Zurich, Lausanne or Montreal. If your child is a good student, you can take more risk and aim for more return in London or Singapore. If your child has been getting mediocre grades, Munich would provide a safe return. Like we are pointing out, your choice of city for higher education is an investment that needs to be carefully studied before making it.

The STC Human Capita Index – City Rankings

This index measures the supply of top graduates by world cities. Only the universities with QS scores of above 80 have been selected in order to produce the "Elite" ranking. The index is an important indicator of competitiveness as it can measure the qualitative supply of labor from universities that are expected to supply graduates with the highest value added. It's no surprise that the top cities are the most competitive in fields of finance, technology, and most other fields where human intelligence weighs the most. It is perhaps relevant to compare that ranking with the STC Economic Power Index, to see which cities oversupply quality labor (e.g., Boston) and those that seem to undersupply quality labor compared to their own consumption (e.g., New York). The "STC Human Capita Indexes - City Rankings" judges cities by the amount of quality graduates they

ges cities by the amount of quality graduates they produce. It's an adjusted sum of the index of all universities in one city, or a city's greater area, factored with the amount of student it produces. The index highlights the ability of a city to produce qualified labour to a high standard. This ranking is very similar to our Economic Power ranking that measu-

2017 STC Higher Education Indexes

res where the economic top performers in term of individuals and companies are located. This is unsurprising as the main factor of production in a service-based economy is human capita. If you produce more and/or better qualified labour, you are bound to be more productive and competitive. The index is a good measure of competitiveness of a city and one both the public and private sector can look at to evaluate how a certain city fairs. As economic competition today is centered around mega cities instead of countries, you can see from the ranking which cities might struggle to be competitive in the high echelon. When it come to producing highly competitive products or services, can a company located outside the top 20 Elite cities really compete with a Samsung or an Apple?

The STC Human Capita Indexes – Country Rankings

This ranking aims to measure the overall access to quality education country-wide. Consistence nation-wide is relevant in the ranking as you need to supply enough places in relation to your population size. Again, no surprise there, Switzerland takes top spot by a good margin, followed by New Zealand. The upper end of the ranking is dominated by Western Europe, primarily because of its abundance of places. An efficient system must facilitate upward mobility and graduation at an average age of below 25. Restricted accessibility to education to the wealthier classes of society reduces the talent to a fraction of the actual pool. Some might have to work for a couple of years in order to save enough money to make that investment (paying for school), thus reducing their overall contribution to society by many years.

Academic accessibility is another factor that can restrict the amount of talent you can access from your pool. Being a top student in secondary school doesn't necessary translate into becoming a highly productive individual in society in the future. Many things can affect a young individual into not perfor-

two rankings change significantly. Northern and Western European countries offer great access to quality education, but many of them disappear in the Elite ranking. Education inequality exists as well, where top schools will be notoriously hard to get into whereas those academically accessible have a significant drop in quality. This is particularly true in France.

The geographic inequality exists as well in a country where the top schools are all in a certain area and part of the population has more restricted physical access to them. France and Russia are good examples, where the best universities are mostly located in the capital. In contrast, Germany and Italy, due to their relatively recent unification, have consistency through most of their territory.

Another indication of a successful higher education system is regarded to be the percentage of the population with tertiary education. This should mirror the result of a great system, but the reality is that it doesn't show the present state of the education system. The data reflects the last 40 years and not the present state. Furthermore, it can be corrupted by migration.

Methodology The Variables

The 2016 QS University Score

The QS University score has been developed by QS in order to rank the world's universities. Here is what they have to say about it: "The QS World University Rankings® are designed to help prospective students make informed comparisons of leading universities around the world. Based on six performance indicators, the ranking assesses university performance across four areas: research, teaching, employability and internationalization.

Each of the six indicators carries a different weighting when calculating the overall scores (see below). Four of the indicators are based on 'hard' data, and the remaining two are based on major global surveys – one of academics and another of employers – each the largest of their kind."

We have taken the top 394 (cut-off QS score of 35) universities in the world from the 2016 QS University Ranking.

The Fees

Fees highlight the average annual fees for undergraduates for both local students and international students. The fees are taken mostly from the QS ranking,

ming highly in secondary school: the growth curve of his brain and how fast he matures, his environment at home, below-average learning abilities, etc. If we judge a person by his teenage years, too many greats would had been classified as rotten apples. This can be especially true in low-income areas where grades can be lower than the country's average. Higher education needs to be inclusive and not exclusive. What will balance that notion is the cost/reward ratio: the use of public funds. Financial accessibility doesn't mean free. It means that the annual cost of university has to be financially accessible in comparison to the median annual household income. Below 10 percent of the median household income is good enough if income inequality is low. If income inequality is high, the costs need to be below 10 percent.

The best country in our list will offer accessible quality education to its population. The Elite ranking only selects the countries that possess universities with a QS score of 80 and over. The results between those

2017 STC Higher Education Indexes

but because in some case the QS ranking is incomplete or imprecise we have added some of our own data. QS takes the average tuition costs. Our data includes the minimum fees that every student is required to pay, such as registration fees and annual contributions. Tuition fees for our data are the general annual costs, usually similar to a Bachelor in Economy, for example. Our data is taken directly from the school's website for 2016.

The Number of Students

The number of students includes both local and international students and these figures are all taken from the QS ranking.

Acceptance Rate

The acceptance rate is not an aggregate measure, as such a thing doesn't exist. It is estimated based on numerous different standards on acceptance, from acceptance rate in the U.S., to SAT scores and specialized tests elsewhere. It's the variable with the highest probability of error and in some cases based on interpretation. It is measured from 1 to 10, with 10 being the highest chance of acceptance. Acceptance is based on local students from the province. The value can change for foreign students or student from out of province.
